# Acknowledgements

This work is based on a publication with the same name published in 2023 in *12th International Conference on Complex Networks and their Applications*.

Part of this work was conducted with support from

- the *University of Washington*
- *Princeton University*
- the *National Science Foundation*

Setup

# Motivation & Applications

- Animal herding: giraffes in Kenya
- Social networks, epidemiological concerns
- Economic agents: funds, companies, people
- Political actors and their voting patterns

# Guiding Question

What is the relationship between the vertices as they evolve over time?

# Previous Approaches

- Aggregation: convert dynamic graph to static one
- Community detection (heuristics)
- Evolutionary clustering
- Online algorithms
- Machine Learning (ML)

# Our Approach: Spatiotemporal Graph $k$ -means (STGkM)

1. Practical + Computable
2. Unsupervised with just one parameter
3. Spatiotemporal smoothness
4. Theoretical guarantees
5. Experimental validation

# The Method

# Mathematical Goal

Can we find a "good" partition of the vertices?

partition of  $k$  elements

# Primer: shortest journey

The shortest *dynamic* path between two vertices traversing one edge at a time.

# Primer: shortest journey

The shortest *dynamic* path between two vertices traversing one edge at a time.

# Mathematical Goal

Can we find a "good" partition of the vertices?

good: minimizes all shortest journeys

# "k-means" Ideal Objective

"participation" regularization matrix

distance based on shortest journey

$$\min_{c \in \mathcal{C}, W \in \mathcal{W}} \sum_{t \in \mathbb{T}} \sum_{u \in V} \sum_{j \in [k]} W_{u,j}^t \cdot \tilde{\delta}^t(u, c_j^t)$$

all possible clusterings over time & space

timesteps

set of vertices

number of elements in our partition

# Relaxed Objective

$$\min_{c, W} \sum_{u \in V} \sum_{j \in [k]} W_{u,j}^t \cdot \delta^t(u, c_j^t)$$

such that  $\delta^{t-q}(c_j^{t-1}, c_j^t) \leq \lambda$ , where  $1 \leq q \leq \gamma$  and  $1 \leq j \leq k$

# Algorithm Overview

1. Solve the relaxed objective (using updated versions of classical techniques)
2. Find cluster membership of each vertex at each timestep
3. Collect information over time for each vertex
4. Use agglomerative (or other) static clustering for each vertex based on cluster membership

Results

# Theorem

For a holding, non-stranding dynamic graph with  $k$  connected components, the partition induced by STGkM are exactly the connected components given sufficient time.

# Finding $k$ with the Elbow Method

# Finding $k$ with the Elbow Method

## Cluster Evolution

Time 1

Time 2

Time 3

# Experimental: Rollcall Votes

1. Vertices: member of US House of Representatives
2. Timestep: each rollcall vote ordered over time
3. Edges: two members are connected at a timestep iff they vote the same way

# Experimental: Number of Clusters

# Experimental: the Swing Votes

## Roll Call Data Cluster Evolution

Vote #10

Vote #20

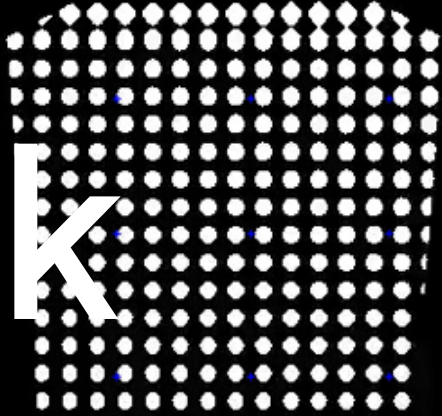

Vote #30
